Work in progress

- Dynamical and brightness astrometry
- Astrophysical sources of excess brightness
 - Simulations
 - Observations
- Conclusion

Context

Ultimate goal: the precise physical characterization of **Earth-mass planets** in the **Habitable Zone (~ 1 AU)** by direct spectro-polarimetric imaging

It will also require a good knowledge of their mass.

Two approaches (also used to find Earth-mass planets):

- Radial Velocity measurements
- Astrometry

Context

Radial Velocity and Astrometric mass measurements have both their limitations .

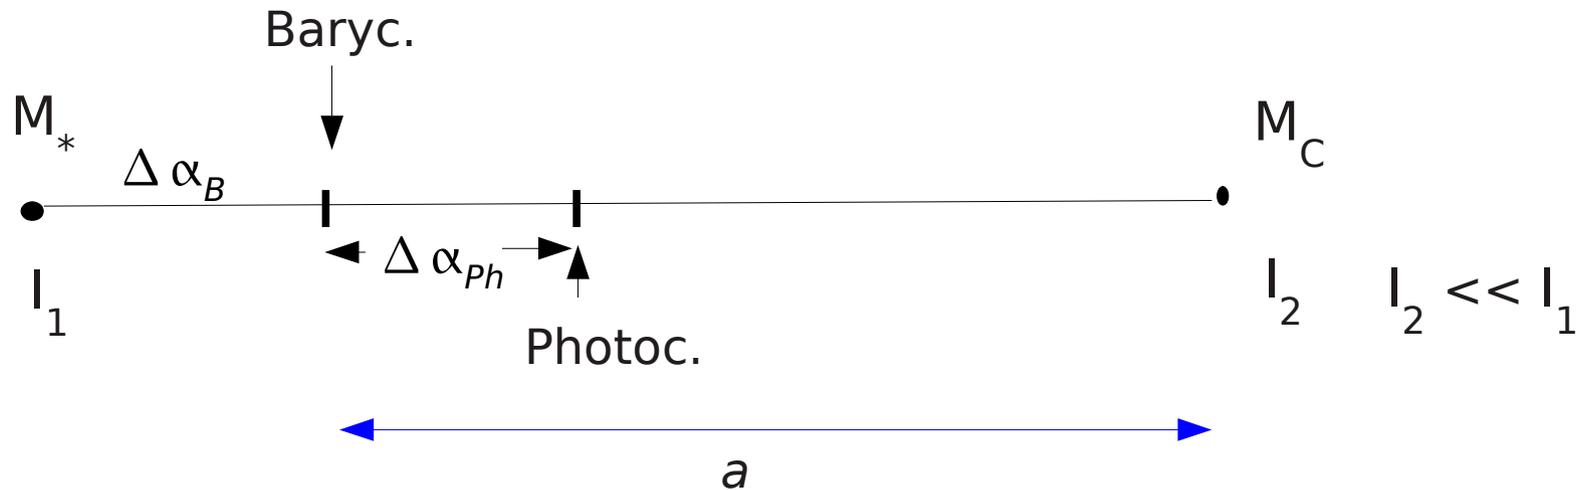

Here we investigate a possible artefact of the astrometric approach for the Earth-mass regime at 1 AU.

==> not applicable to Gaia or PRIMA/ESPRI

Very simple idea:

can a blob in a disc mimic the astrometric signal of an Earth-mass planet at 1 AU?

Dynamical and brightness astrometry

- Dynamical astrometry

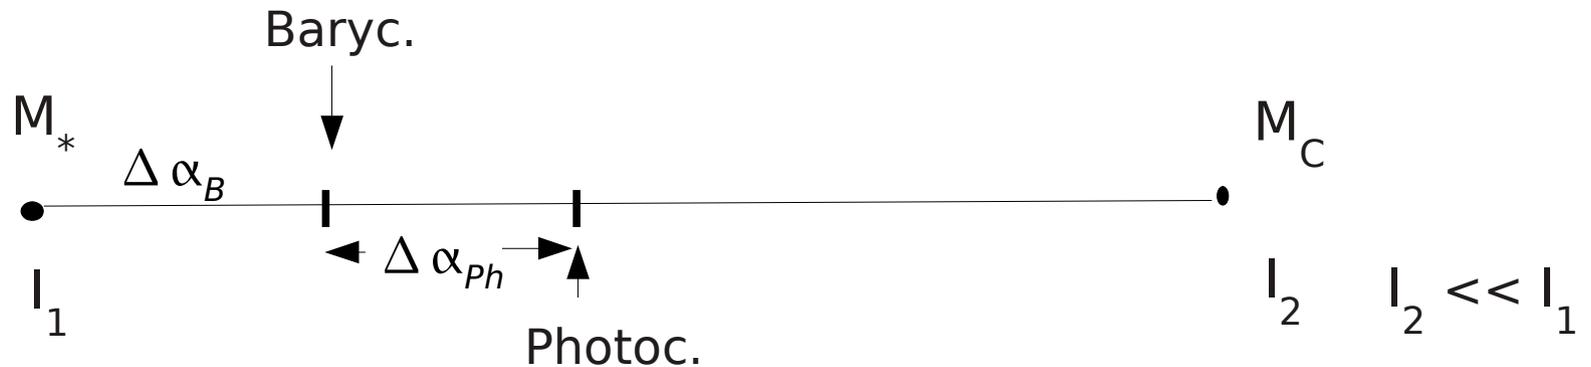

$$\Delta \alpha_B = \frac{M_C}{M_*} \frac{a}{D}$$

- Brightness (photometric) astrometry

$$\Delta \alpha_{ph} = \frac{I_2}{I_1} \frac{a}{D} - \Delta \alpha_B = \left(\frac{I_2}{I_1} - \frac{M_C}{M_*} \right) \frac{a}{D}$$

Question: can $\Delta \alpha_{ph}$ be $>$ $\Delta \alpha_B$?

Dynamical and brightness astrometry

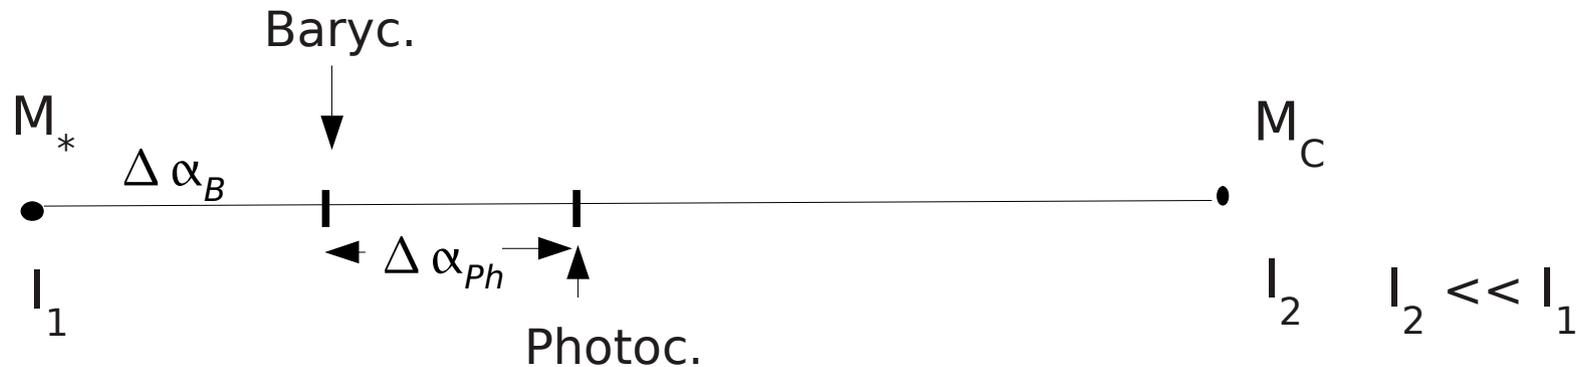

- $$\Delta\alpha_B = \frac{M_C}{M_*} \frac{a}{D} \sim 3 \times 10^{-6} \frac{a}{D}$$

for a 1 Earth-mass planet

- $$\Delta\alpha_{ph} = \frac{I_2}{I_1} \frac{a}{D} - \Delta\alpha_B \sim \frac{I_2}{I_1} \frac{a}{D}$$

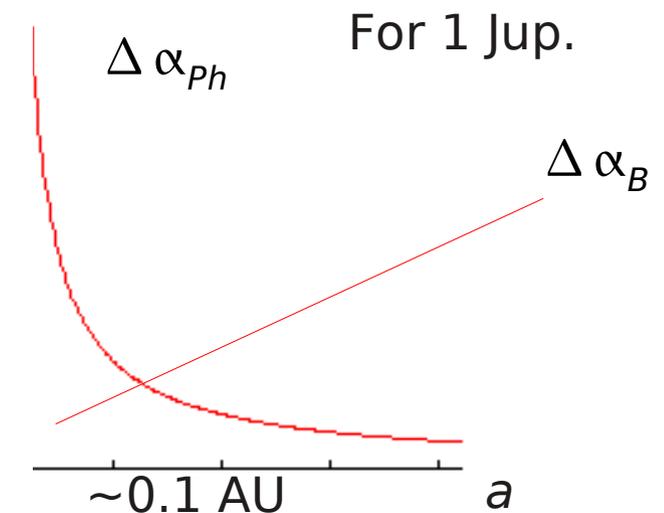

Can I_2/I_1 be $> 3 \times 10^{-6}$?

Dynamical and brightness astrometry

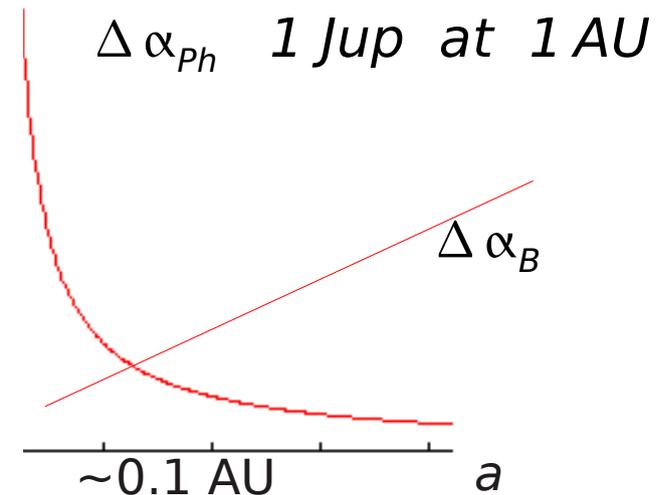

- $$\Delta \alpha_B = \frac{M_C a}{M_* D} \sim 3 \times 10^{-6} \frac{a}{D}$$

- $$\Delta \alpha_{ph} \sim \frac{I_2 a}{I_1 D} = \frac{A}{4} \left(\frac{R_C}{a} \right)^2 \frac{a}{D} = \frac{A R_C^2}{4 a D}$$

Dynamical and brightness astrometry

- $\Delta \alpha_B = \frac{M_C a}{M_* D} \sim 3 \times 10^{-6} \frac{a}{D}$
- $\Delta \alpha_{ph} \sim \frac{I_2 a}{I_1 D} = \frac{A}{4} \left(\frac{R_C}{a} \right)^2 \frac{a}{D} = \frac{A R_C^2}{4 a D}$

Can $\Delta \alpha_{ph}$ be larger than $\Delta \alpha_B$ at 1 AU ?

Condition: $A/4(R_C^2/1AU) > 3 \cdot 10^{-6} \sim 100 R_{Jup}^2 \implies AR_C^2 > 50 R_{Jup}^2$

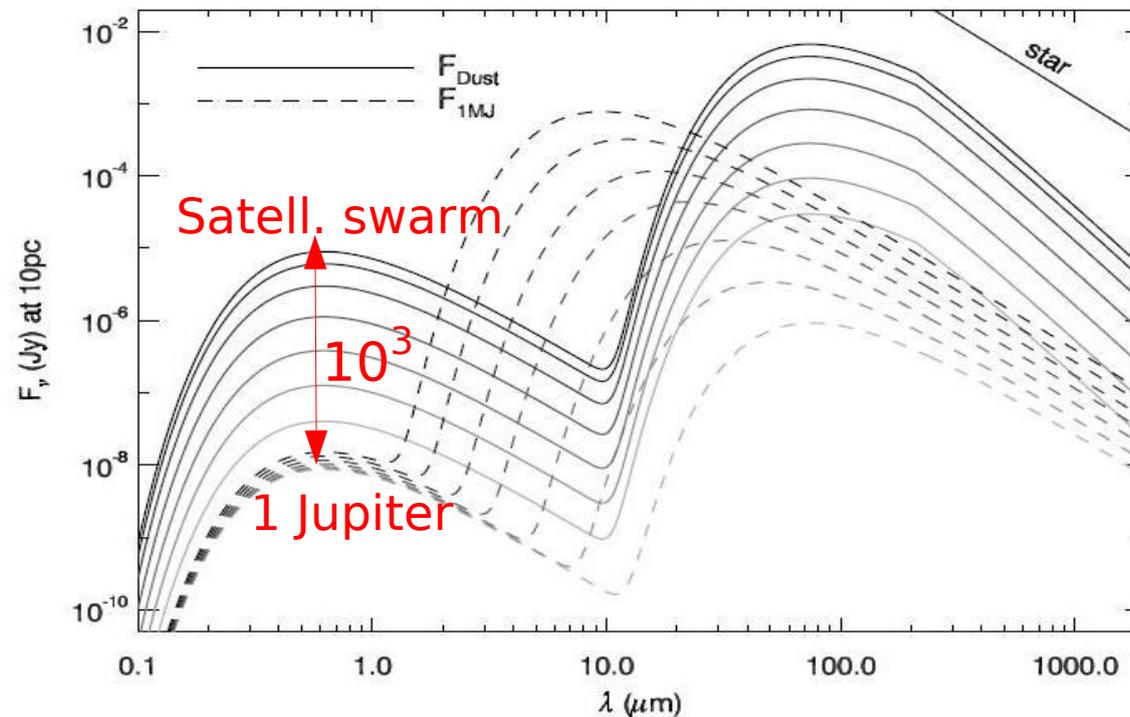

Explore sources of low mass objects brighter than 50 Jupiter at 1 AU

Past experience: Anything can happen in exoplanetology

Astrophysical sources of brightness excess

- Simulations

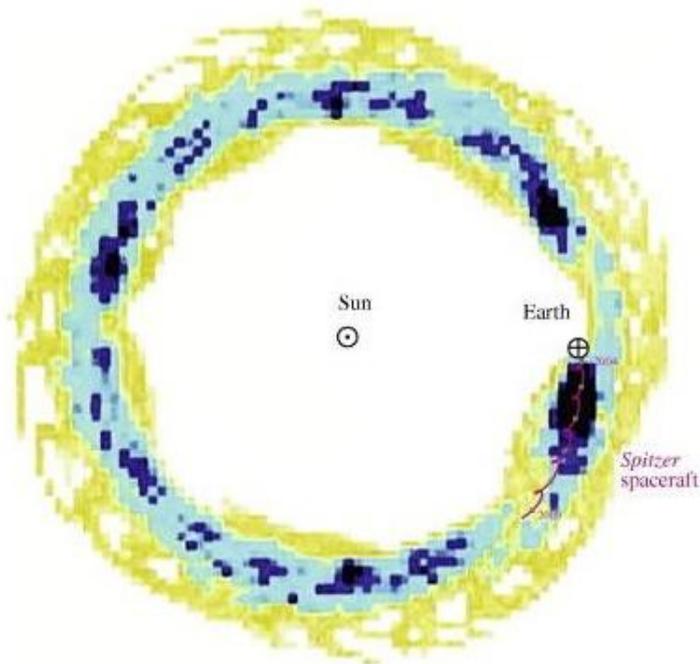

"Irregular Satellite Swarms: Detectable Dust around Solar System and Extrasolar Planets" Kennedy & Wyatt, MNRAS, 412, 2137, 2011

Astrophysical sources of brightness excess

- Observations

- Earth's dust ring (Reach, Icarus, 209, 848, 2011)

About $N = 10$ blobs $0.1 \text{ AU} \times 0.1 \text{ AU}$
 $= 200 \times 200 R_{\text{Jup}}^2$

Assuming a dust albedo 0.01,

$$AR_C^2 > \sim 10^3 R_{\text{Jup}}^2$$

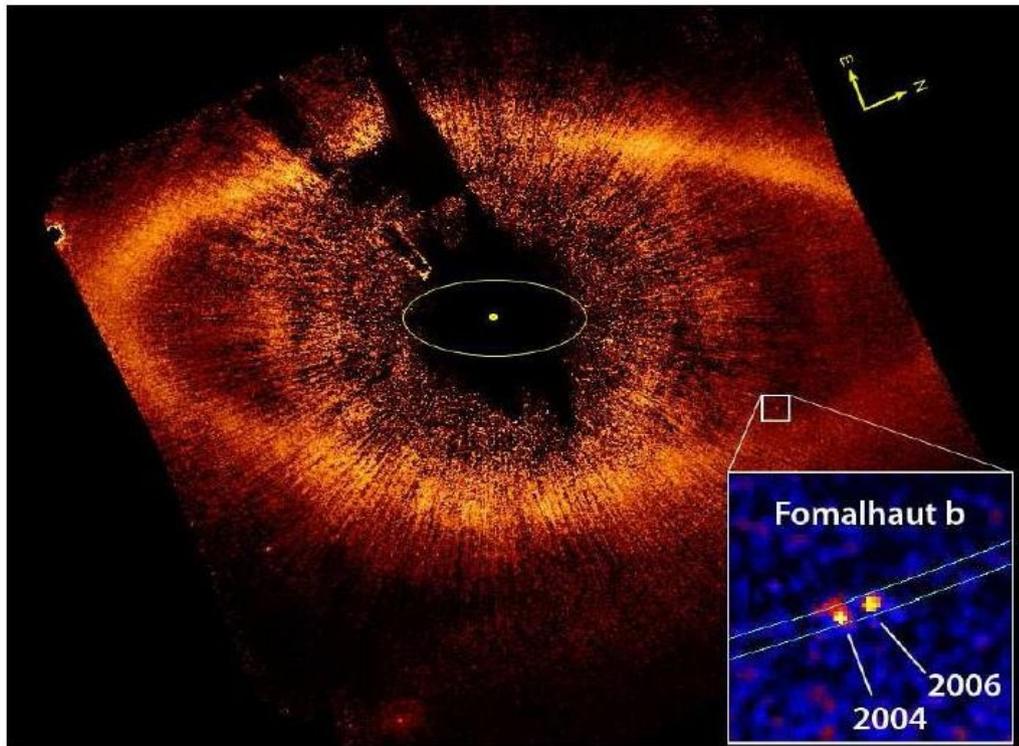

for each blob and at 1 AU:

$$\Delta \alpha_{\text{ph}} \sim \frac{1}{\sqrt{N}} \frac{A}{4} \left(\frac{R_C}{a} \right)^2 \frac{a}{D} = \frac{A}{12} \frac{R_C^2}{aD} = 0.015 \frac{R_{\text{Jup}}}{D}$$

$$\sim \Delta \alpha_B \text{ for } 1 M_{\text{Earth}} \text{ at } 1 \text{ AU}$$

Astrophysical sources of brightness excess

- Observations
 - Fomalhaut b

Companion 400 brighter than a Jupiter at 100 AU

Interpretation: dust cloud around a planet

Open question:
Can such dust clouds exist at 1 AU?

Conclusion

The photocenter variation can possibly be larger than the 1 Earth mass astrometric signal at 1 AU.

To measure terrestrial planet masses at 1 AU, astrometric measurements must be combined with high contrast high angular resolution imaging
